

Python & SQL Troubleshooting

Fictional order reporting workflow: exception handling, idempotency and join-fanout repair.

UNCORRECTED QUERY (CAD)	$12,098.00
CORRECTED QUERY (CAD)	$8,960.00
REVENUE OVERSTATEMENT	$3,138.00
AUTOMATED TESTS	3 passing

PROBLEM

Python import crashed when it encountered dollar-formatted strings. Import retries duplicated items; joining captured payments multiplied line-item revenue.

APPROACH

Implemented safe money parsing, date normalization, unique item IDs and status validation. Rewrote SQL using EXISTS to prevent a many-to-many reporting error.

VERIFICATION

Runnable broken and fixed scripts, SQL query comparison, generated SQLite database, audit JSON and unit tests. Output is illustrative, not payment-grade accounting.
